## Transport studies across the lung / bowel epithelial barrier

Method name	Determination of cumulative mass across a cell barrier (lung cells / in- testinal cells)
Organ system	Lungs / Bowel
Subject area	Drug development
Area of application	Formulation development, Testing of bioequivalent properties
Relation of the method	Replacement & Reduction, Pharmacological prediction on drug ab-
to the 3Rs	sorption
Figure	apicalepithelial cells basolateraltest solution ↓ diffusion
	The figures show a transwell <sup>™</sup> with a test solution for transport across an epithelial cell barrier (upper figure) and a plot of the cumulative
	mass of the test substance over time (lower figure).
Brief description	The transwell <sup>™</sup> model allows the representation of the cumulative mass of a test substance across a confluent epithelial monolayer. Calu-3 cells are used for pulmonary issues, whereas intestinal testing requires Caco-2 cells. However, the system can be applied to all cell types that form a confluent monolayer through, e.g., tight junctions. The integrity of the cell barrier will be assessed using transepithelial resistance (TEER) measurements. Plotting the cumulative mass in the apical compartment against time allows the calculation of an apparent permeability coeffi- cient. The study gives a first prediction of drug absorption.
Theme-based funding	INNO-KOM project "Kombipulmonal" (FKZ 49MF200045).
